1 Introduction

RNASeq is a very vast topic and tons of papers have been and are being written on the topic. The following is just an overview.

Originally the idea was proposed by Mortazavi *et al.* (2008). Although several modification of the original idea have been developed, the basics did not change. In this handout will use the latest in the RNASeq methodology through the use of software called RSEM (Li and Dewey, 2011).

2 Normalization of RNASeq data

People have proposed several methods of normalization of RNASeq data. For a comparison see Dillies *et al.* (2013).

3 Datasets

Every differential expression measurement should have biological replicates. For demonstration, we will use only 1 replicate for two biological conditions. But in real life, this should never be used. We will use two small datasets from Illumina Body Map project. These are samples prepared from adrenal gland and brain and only from chromosome 19. You can download the datasets here:

https://github.com/cb2edu/CB2-101-BioComp/raw/2018/10-RNASeq/data/rnaseq_data.tar.gz

Unzip the file.

4 Required software

1. Install on Linux the following packages: `openssl openssl-devel curl curl-devel`
2. It was previously fairly complicated to install bioconductor packages. But if you're using R version 3.5 or above, a package from CRAN can make the process easier. Run in R console:

```
install.packages("BiocManager")
```

Use `BiocManager::install()` function to install R packages.

5 STAR

STAR is a modern fast aligner for RNASeq data to reference genome.

```
wget https://github.com/alexdobin/STAR/archive/2.5.1b.tar.gz
tar -xvzf 2.5.1b.tar.gz
cd STAR-2.5.1b
make
```

Put the software in your path

```
cd Linux_x86_64_static/
export PATH=$PATH:`pwd`
```

Prepare the reference genome:

```
mkdir hs
STAR --runThreadN 8 --genomeDir hs --runMode genomeGenerate \
    --genomeFastaFiles chr19.fa --sjdbGTFfile human_chr19.gtf
```

Now create the alignment. There is a special option for STAR to create a "transcriptome alignment" that could be fed directly to RSEM.

```
STAR --runThreadN 8 --genomeDir hs --readFilesIn adrenal_R1.fq \
    adrenal_R2.fq --quantMode TranscriptomeSAM
```

6 RSEM

RSEM is a cutting-edge RNASeq analysis package that is an end-to-end solution for differential expression, and simplifies the whole process. It also introduces a new more robust unit of RNASeq measurement called TPM.

6.1 Installing RSEM

```
wget http://deweylab.biostat.wisc.edu/rsem/src/rsem-1.2.19.tar.gz
tar -xvzf rsem-1.2.19.tar.gz
cd rsem-1.2.19/
make
export PATH=$PATH:`pwd`

# Install ebseq
module load R/R-3.1.2
make ebseq
cd EBSeq/
export PATH=$PATH:`pwd`
```

6.2 Prepare reference

```
rsem-prepare-reference --gtf human_chr19.gtf chr19.fa rsem/chr19
```

6.3 Calculate expression directly from STAR output

```
rsem-calculate-expression --no-bam-output --paired-end \
  --bam Aligned.toTranscriptome.out.bam rsem/chr19 adrenal
```

6.4 Simpler way to estimating expression

```
rsem-prepare-reference --gtf human_chr19.gtf --star --star-path \
  ../STAR-2.5.1b/bin/Linux_x86_64_static -p 8 chr19.fa hs/chr19
rsem-calculate-expression --paired-end --star --star-path \
  ../STAR-2.5.1b/bin/Linux_x86_64_static/ -p 8 adrenal_R1.fq \
  adrenal_R2.fq hs/chr19 adrenal_rsem
rsem-calculate-expression --paired-end --star --star-path \
  ../STAR-2.5.1b/bin/Linux_x86_64_static/ -p 8 brain_R1.fq brain_R2.fq \
  hs/chr19 brain_rsem
```

6.5 Differential expression

```
rsem-generate-data-matrix adrenal_chr19.genes.results human_chr19.genes.results \
  >diff-brain-adrenal.txt
rsem-run-ebseq diff-brain-adrenal.txt 1,1 expression.results.txt
rsem-control-fdr expression.results.txt 0.05 expression_final.txt
```

And we have our differentially expressed genes.

6.6 Volcano plot

Volcano plot is a good way to show the differentially expressed genes. For that we need the p-value for the differentially expressed genes and the the fold change. Given by “PPEE” and “RealFC” values.

```
data<-read.table("expression.results.txt")
plot(log2(data$RealFC),data$PPDE,xlab="Fold change",ylab="P-value")
```

7 EDGER

For EDGER we need a count table data for mutiple sample. The supplied pnas_expression.txt is a sample file derived from the paper here: <https://www.ncbi.nlm.nih.gov/pubmed/19088194>.

```
raw.data <- read.table("../data/pnas_expression.txt",header=T)
head(raw.data)
counts <- raw.data[ , -c(1,ncol(raw.data))]
rownames(counts) <- raw.data$ensembl_ID
colnames(counts) <- paste(c(rep("C_R",4),rep("T_R",3)),c(1:4,1:3),sep="")

library(edgeR)
group <- c(rep("C", 4) , rep("T", 3))
cds <- DGEList( counts , group = group )
```

```

cds <- calcNormFactors(cds)
design <- model.matrix(~group)
y <- estimateDisp(cds, design)
fit <- glmQLFit(y, design)
qlf <- glmQLFTest(fit, coef=2)
topTags(qlf)

```

8 DESEQ2

```

suppressPackageStartupMessages(library(DESeq2))
counts <- read.table("../data/pnas_expression.txt", header = T)
row.names(counts) <- counts$ensembl_ID
counts <- as.matrix(counts[,-c(1, ncol(counts))])
counts <- counts[rowSums(counts) != 0,]
coldata <- data.frame(condition=c(rep("C", 4), rep("T", 3)))
row.names(coldata) <- colnames(counts)
#coldata <- as.matrix(coldata)
dds <- DESeqDataSetFromMatrix(countData = counts, colData = coldata, design = ~ condition)

```

```

## Warning in DESeqDataSet(se, design = design, ignoreRank): some variables in
## design formula are characters, converting to factors

```

```

dds <- estimateSizeFactors(dds)

```

Get the size factor estimate

```

#get the sizefactors
sizeFactors(dds)

```

```

##      lane1      lane2      lane3      lane4      lane5      lane6      lane8
## 0.7912131 0.9433354 1.1884939 1.2307145 1.4099376 1.4224762 0.5141056

```

To get the count normalized count table:

```

head(counts(dds, normalized=T))

```

```

##              lane1      lane2      lane3      lane4      lane5      lane6

9 Gene set enrichment analysis

Consider a bag full of marbles (total N) containing K green marbles and $(N - K)$ red marbles. If we draw a sample of n from this bag, the probability of getting exactly k green marble is given by *Hypergeometric distribution*.

$$Prob(X = k) = \frac{\binom{K}{k} \binom{N-K}{n-k}}{\binom{N}{n}}$$

This is exactly the scenario of finding a pathway or gene-ontology hits with differentially expressed gene sets. In this case:

N = total number of genes in the genome
 n = number of differentially expressed genes (degS) with significant p-value
 K = Number of genes in a pathway or ontology
 k = overlap between degs and that pathway

To calculate this probability in R we need to calculate the cumulative distribution of (*overlap* $\geq k$).

```
phyper(q=k, m=K, n=N-K, k=n, lower.tail = FALSE)
```
